# Life Cycle Assessment of Metal Packaging in Europe 

## EXECUTIVE SUMMARY - June 2022

Metal Packaging Europe (MPE) is the association of European producers of rigid metal packaging bringing together over 300 manufacturers, and their national associations, which employs over 60,000 people in 23 European countries.

With growing demand for sustainable production and consumption, MPE is fully committed to provide objective and reliable information about the environmental performance of rigid metal packaging. For this reason, MPE commissioned an in-depth Life Cycle Assessment (LCA) conducted by RDC Environment and reviewed by Solinnen according to the requirements of the international standard ISO 14040/44.

Based on 2018 production data, the study covers the life cycle of metal packaging produced in Europe, from raw material extraction through manufacturing and end-of-life (see Figure 6) and the following packaging categories: aluminium beverage cans, aluminium and steel food cans, steel aerosol, steel general line, steel closures and steel speciality packaging.

Production data was collected from multiple manufacturing plants across Europe resulting in a coverage of the European metal packaging production of approximately $42 \%$ for steel packaging and $82 \%$ for aluminium packaging, according to market estimates. The following members of Metal Packaging Europe submitted data for the study: Ardagh Group, Ball Packaging, Colep, Crown Packaging Europe, Envases, Eviosys, Massilly, Pelliconi, Sarten, Silgan, and Trivium Packaging.

The environmental performance of metal packaging is calculated according to the functional unit, which is one thousand $(1,000)$ units of packaging, and described by 16 impact categories recommended by the Environmental Footprint methodology of the European Commission (see Table 5).

The results of the Climate Change impact are listed in the tables below per one unit of packaging and its average weight; the full range of impact assessment is reported in Figure 7 and Figure 8. More details are provided in the Methodological Report available at MPE website (link).

Avenue des Arts 41 1040 Brussels Belgium

E info@metalpackagingeurope.org T +32 28970490
W www.metalpackagingeurope.org

On average across the aluminium packaging categories, the contribution to the Climate Change impact of the can manufacturing process is $\sim 22 \%$ whereas the contribution of the raw material production and transport plus the end-of-life (recycling \& disposal) is $\sim 62 \%$. The transport to fillers accounts for $\sim 14 \%$ and the secondary and tertiary packaging for $\sim 3 \%$.

On average across the steel packaging categories, the contribution to the Climate Change impact of the can manufacturing process is $\sim 22 \%$ whereas the contribution of the raw material production and transport plus the end-of-life (recycling \& disposal) is $\sim 68 \%$. The transport to fillers accounts for $\sim 9 \%$ and the secondary and tertiary packaging for $\sim 1 \%$.

In the above tables the values of the "End-of-Life (recycling \& disposal)" phase are negative, representing an environmental benefit. By recycling the cans into the same material system from which they were generated (socalled closed loop approach) emissions due to primary metal production are avoided. Emissions from secondary metal production are lower than those from primary metal production.

On average across the metal packaging categories, recycling metal packaging at the rates used in the study (i.e. $76 \%$ for beverage cans and $84 \%$ for steel packaging) reduces the greenhouse gases emissions of the primary production respectively by around $68 \%$ for aluminium and $44 \%$ for steel. Made from permanent materials, metal packaging is a perfect fit for a Circular Economy: both aluminium and steel can be recycled over and over again without losing their intrinsic properties, allowing the materials to remain in the economy and therefore reducing the need for primary raw materials.

When compared to the previous LCAs ${ }^{1}$, the study records significant reductions in greenhouse gases emissions, confirming the industry's commitment to reduce carbon emissions and to decouple production from its carbon footprint. The main factors which have made this progress possible are:

- improvements taking place in raw material production over time;
- improvements in the can manufacturing processes, including an increase in energy and resource efficiency ${ }^{2}$;

[^0]Page | 3

- a reduction in can weight, of $2 \%$ for aluminium beverage cans, for example, and $1 \%$ for steel food cans; and
- an increase in aluminium and steel packaging recycling rates, with the beverage can recycling rate currently at $76 \%$ and steel packaging reaching 84\%.

## Avenue des Arts 41 1040 Brussels Belgium

Metal
Packaging Europe

From a Climate Change perspective, results for the aluminium beverage cans ( 330 ml ) show that the impact on Climate Change has been reduced by around $50 \%$ over the 2006-2018 period.

Figure 1 Climate Change impact reduction over the 2006 - 2018 period for average aluminium beverage cans ( 330 ml )

For steel packaging, results show that over the 2000 - 2018 period the impact on Climate Change has been reduced by:

- over 30\% for food cans and general line packaging;
- just under 20\% for aerosol can (2006-2018);
- over $40 \%$ for closures; and
- over $10 \%$ for speciality packaging.

## Metal Packaging Europe GIE

## Avenue des Arts 41 1040 Brussels Belgium

A specific analysis was carried out on the tinplate production to assess its Climate Change reduction over time: for this purpose, WorldSteel data was used which show an $8 \%$ reduction in greenhouse gases emissions over the $2013-2019^{3}$ period. This improvement is not accounted in the above diagrams because the same data of the previous studies for aluminium and steel production (respectively provided by European Aluminium and APEAL) have been used in order to compare the results over time.

The analysis of the Climate Change reduction over time for the aluminium production was assessed in the previous LCA study, showing a $3 \%$ reduction in greenhouse gases emissions over the 2006-20164 period.
